

Using the HC-06 Bluetooth Module

Posted on [June 19, 2013](#) by [Erich Styger](#)

20 Votes

After [my first post using a Bluetooth module](#), things have evolved a bit. The challenge with these Bluetooth modules is: they look the same, but having different firmware. I did not fully realize that until I have ordered another bluetooth module from [dx.com](#):

— DX.com Bluetooth Module (HC-06)

That module comes already on a carrier, so I assumed I can use the same driver as for my other module. I was wrong 😞.

HC-05 or HC-06

My earlier module which I received from another source (without an adapter, [see this post](#)) has a different firmware on it, known as HC-05, while my DX.com module has a HC-06 firmware. To be clear: the modules are the same, but the software/firmware on it is different, and the firmware uses the pins differently too 😞

— HC-06 and HC-05 (Source Wavesen Data Sheet)

💡 Check out this post which explains how to re-program the firmware of the device with firmware programming adapter: <http://byron76.blogspot.ch/2011/09/hc05-firmware.html>

The HC-05 has the 'full' firmware on it: many AT commands, and can be both master and slave module. The HC-06 firmware on the other hand only can be a slave device, with very limited AT commands.

Or in other words:

- The **HC-05** module can build a connection to other modules. E.g. a Robot being a master and connecting to slave bluetooth module. Or in slave mode to make a wireless bridge to a notebook.
- The **HC-06** module only can be a slave. This makes it only useful for say connecting a notebook as a master to a robot with a slave module e.g. for a wireless serial bridge.

For most use cases the HC-06 is enough, as typically I want to have a wireless UART connection to my devices from my notebook.

JY-MCU V1.5 Module

Below is an image of the JY-MCU HC-06 (JY-MCU V1.5) module. The module came with a 4-pin header, and I have added the pins for STATE and KEY, and removed the plastic around the module to get access to the pins:

— HC-06 Top Side

Pins

On the bottom side there are labels for the signal direction and voltage levels:

— JY-MCU BT_BOARD V1.05 Bottom Side

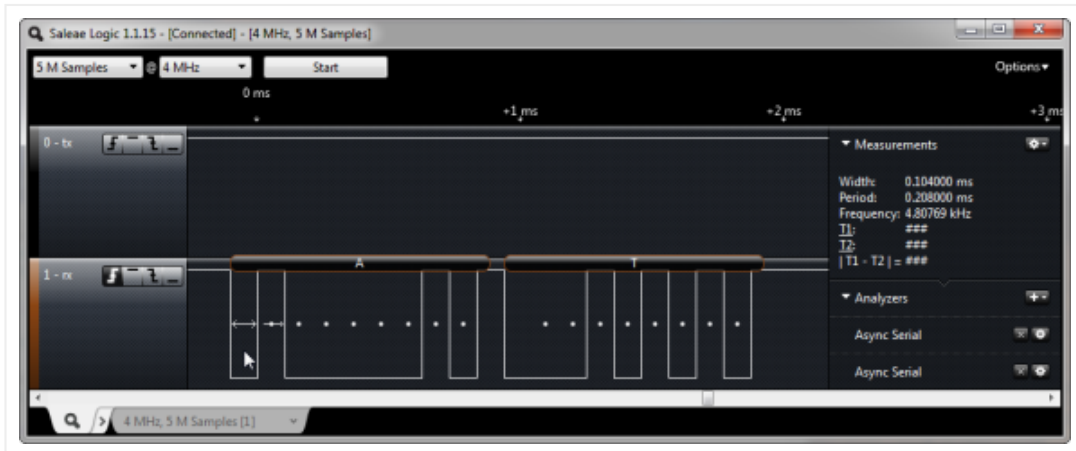

- **KEY:** according to the data sheet, I need to pull-up this pin while power-on-reset of the module to enforce AT mode. I have not been able to verify this yet. I have been told that some modules have this pin not connected at all?
- **VCC** is indicated in the range of 3.6V-6V. The module worked for me both with 3.3V and 5V.
- **GND:** Ground
- **TXD:** serial *output* of the module, to be connected to RX of the microcontroller. Note that this signal is using 3.3V logic level
- **RXD:** serial *input* of the module, to be connected to the TX of the microcontroller. Note that this signal is using 3.3V logic levels.
- **STATE:** connected to LED2 (Pin32) of the module, but no meaning? At least on my module the pin was always low, regardless if paired or not.

Different AT commands

On the HC-05 module, I send “AT\r\n” to the device, and then it responds with “OK\r\n”.

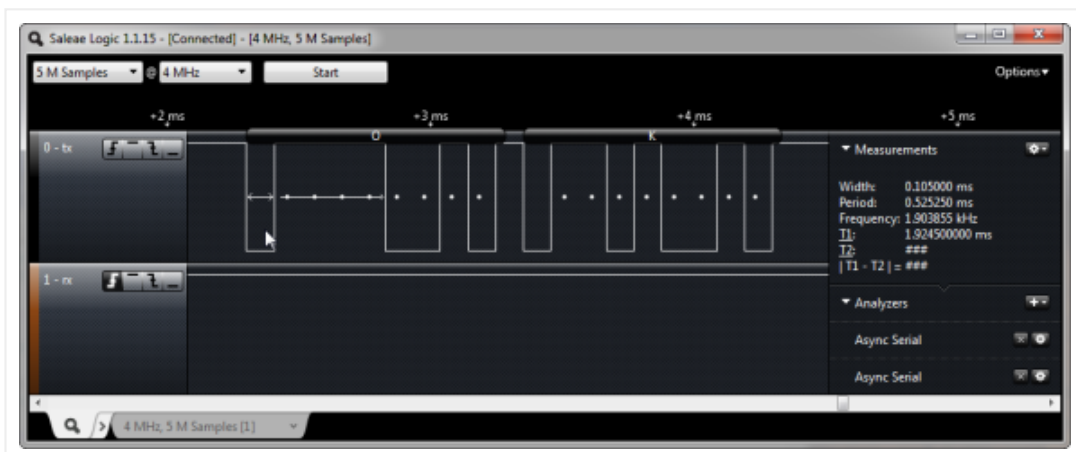

But on the HC-06, the protocol is different 😞 I need to send “AT” (without the new-line characters), and I receive “OK” (without the new-line characters).

The logic analyzer shows this behaviour too: AT command sent to the device:

— AT Command sent to Device

OK response from the device with no “\r\n” at the end:

— OK Response from the Device

The missing “\r\n” is present for all commands of the HC-06 firmware. As as this is not enough, there are very few command possible. The table below shows all the HC-06 firmware commands with the response:

COMMAND	RESPONSE	COMMENT
AT	OK	Used to verify communication
AT+VERSION	OKlinvorV1.8	The firmware version (version might depend on firmware)

AT+NAMExyz	OKsetname	Sets the module name to "xyz"
AT+PIN1234	OKsetPIN	Sets the module PIN to 1234
AT+BAUD1	OK1200	Sets the baud rate to 1200
AT+BAUD2	OK2400	Sets the baud rate to 2400
AT+BAUD3	OK4800	Sets the baud rate to 4800
AT+BAUD4	OK9600	Sets the baud rate to 9600
AT+BAUD5	OK19200	Sets the baud rate to 19200
AT+BAUD6	OK38400	Sets the baud rate to 38400
AT+BAUD7	OK57600	Sets the baud rate to 57600
AT+BAUD8	OK115200	Sets the baud rate to 115200
AT+BAUD9	OK230400	Sets the baud rate to 230400
AT+BAUDA	OK460800	Sets the baud rate to 460800
AT+BAUDB	OK921600	Sets the baud rate to 921600
AT+BAUDC	OK1382400	Sets the baud rate to 1382400

That's it.

Firmware Timing

As this is not enough, my driver did not work even with the new commands implemented. The HC-05 firmware as sending a response back in less than 300 ms, while the HC-06 firmware needs more than 500 ms until there is a response:

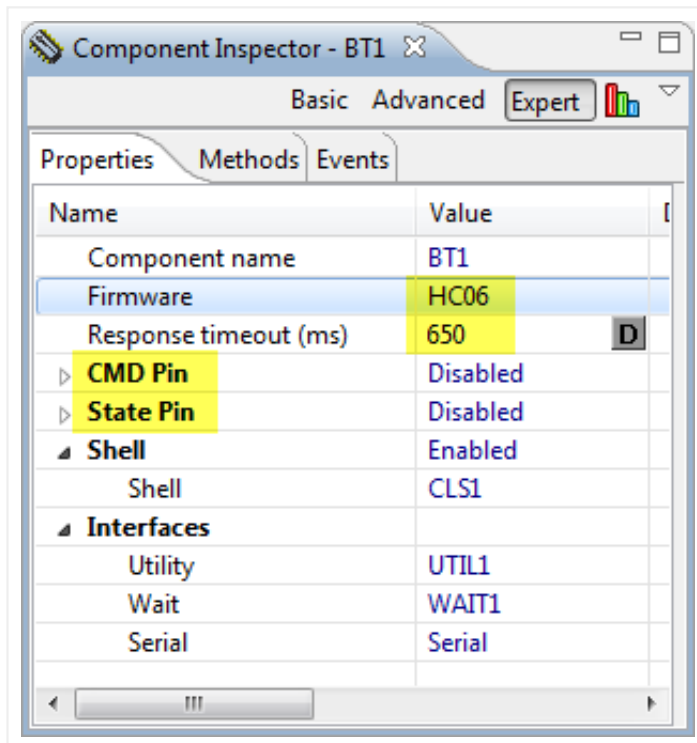

— Delay between Command and Response

So for this I had to introduce a user configurable delay in the component.

Processor Expert Component

With this knowledge, the Processor Expert Bluetooth component has been updated to support both the HC-05 and HC-06 firmware:

— Bluetooth Component Supporting HC-05 and HC-06

- **Firmware** to select between HC-05 and HC-06
- Configurable **Response Time** if the module needs longer for commands
- Optional **State** and **CMD** pins

If the HC-05 firmware is selected, then the component automatically disables the functionality methods not present/supported in the firmware (grayed out methods):

- BT1:Bluetooth_EGBT
 - Serial1:AsynchroSerial[Bluetooth_EGBT\Serial]
 - Init
 - Deinit
 - GetLastError
 - GetErrorString
 - SendATCommand
 - StdCmd
 - StdOKCmd
 - QueryString

— Bluetooth Module Methods

Command Line Interface

The Processor Expert component features an optional command line interface:

— HC-o6 Shell Commands

With this, I can change the pairing pin, device name or baud, beside of sending AT commands or sending a string over the wireless bridge.

💡 *Changing the pairing/name/baud will be effective after resetting the device. Keep in mind if you change the baud, this will change the baud as well between the module and the microcontroller.*

The 'status' command issues an AT command to the device to see if it responds, plus shows the firmware version:

— BT1 Status with Module Firmware

! *Status and AT commands can only be used if the device is not paired yet (means: while the red LED is blinking).*

Connecting to the Bluetooth Module

The Bluetooth module runs the SPP (Serial Protocol over Bluetooth) protocol. So any device supporting SPP can connect to it. On a PC this looks like a virtual COM port. I show here the steps for Windows (running Windows 7).

! *It seems that Apple (iPhone, iPad, etc) does ***not*** support SPP, so connecting with an iPhone is not possible. Android (which I did not try) should work, or any PC machine with Bluetooth.*

Before connecting, make sure the module is powered and ready to pair. The red LED on the module indicates the status:

- blinking: ready to pair
- steady on: paired

From the Device Manager, select 'Add a Device':

— Device Manager with Add a Device

Then the new device should show up:

— Add a device Dialog

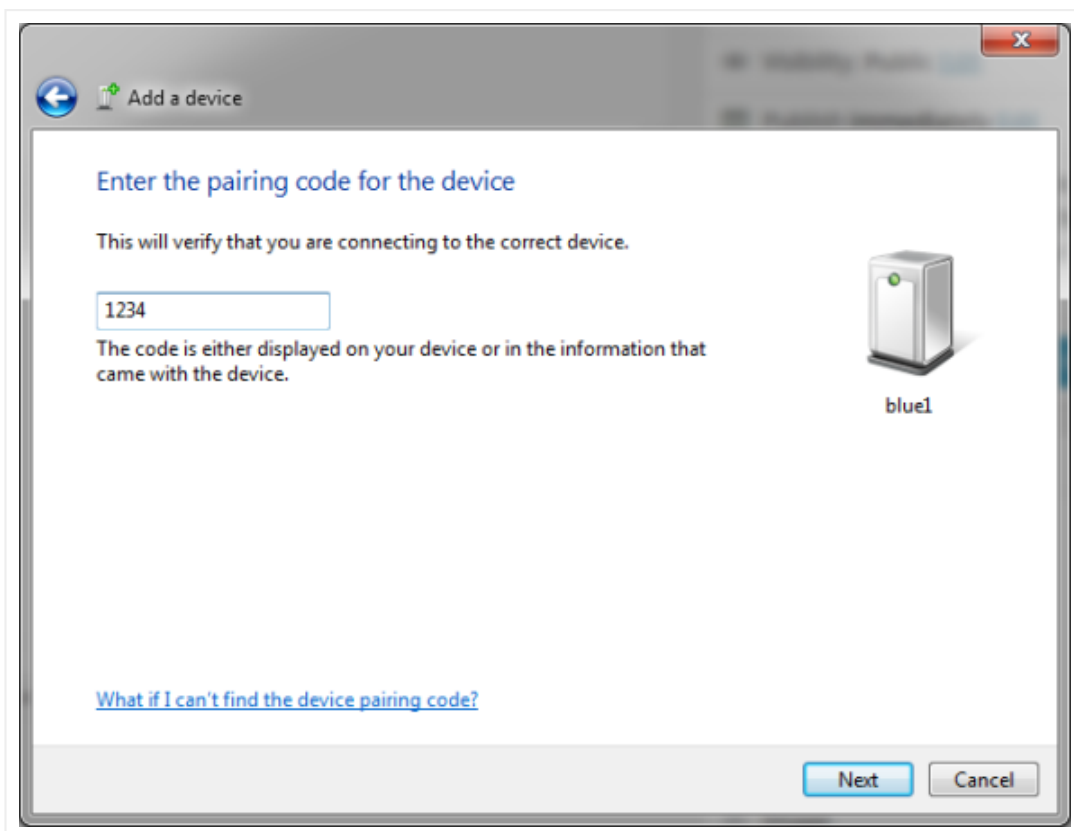

💡 *the name of the device shows here for me 'blue1', as I have named it as such. But it might show up for you as 'linvor' (default) or 'other'.*

Select the device and press 'Next'. In the next dialog select 'Enter the device's pairing code':

- Enter the device's pairing code

The default pairing code is 1234:

- Enter the pairing code for the device

Pressing next, and device drivers will be installed:

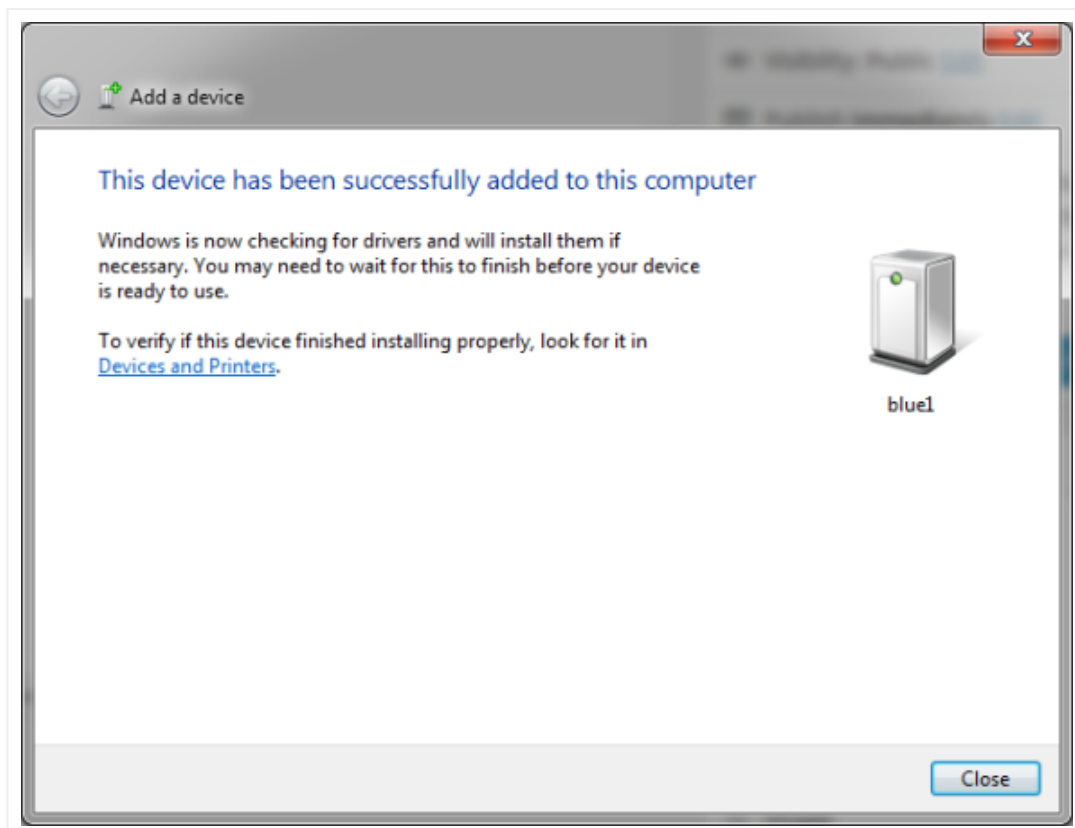

- Installing device drivers

Then the device is ready to use:

- Your Device is ready to use

And the confirmation dialog shows up:

- This device has been successfully added to this computer

COM Port used by Device

Checking the properties on the newly added device shows that it supports SPP. And it shows the virtual COM port used:

— Device Services

! *Note that if I check the COM ports in the device manager, then I see that actually two COM ports have been added. Only the one shown above with the SPP protocol will work. It is unclear to me why there is a second port?*

Connecting to the Wireless Bluetooth Bridge

Using that COM port shown for the SPP service, I can connect with a terminal program on the host PC to my board. Basically this gives me a wireless bridge over Bluetooth to my board. So from my PC I can open a terminal window and type in some commands, which are parsed by the Shell on the FRDM board, and it responds back to the terminal on the PC:

— Wireless Bluetooth Bridge Connection

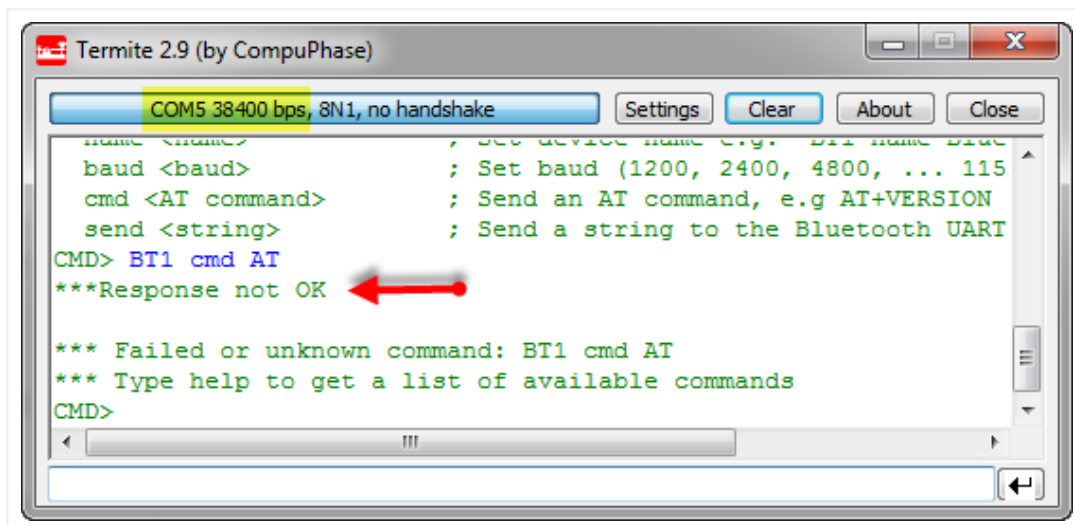

! Make sure you use the COM port used for the SPP service, and that it matches the baud settings of the communication between the microcontroller and the Bluetooth module. I'm using above the default of 9600 baud. It is possible to change/increase the baud as explained above, as 9600 is not very fast. Only be sure that you not exceed the baud to a value which cannot be handled by your PC. It should work ok up to a baud of 115200.

Once connected, the red LED on the Bluetooth module is always on.

- Pairing LED

While connected, the module is in 'transparent' mode, and does not accept AT commands. Below is an example where I try to send an AT command from the microcontroller while the Bluetooth module is connected to the host PC:

- Trying to send AT commands from the microcontroller while connected to PC

Instead, what I send to the UART ends up transparently on the host PC:

Wireless Bridge

Everything I send to the virtual COM port ends up on the Bluetooth module, which then sends the commands to the microcontroller using the RX and TX connection between the microcontroller and the module. With this, it is very easy to send/receive commands using the Processor Expert Shell component, and the implementation are just a few lines:

```

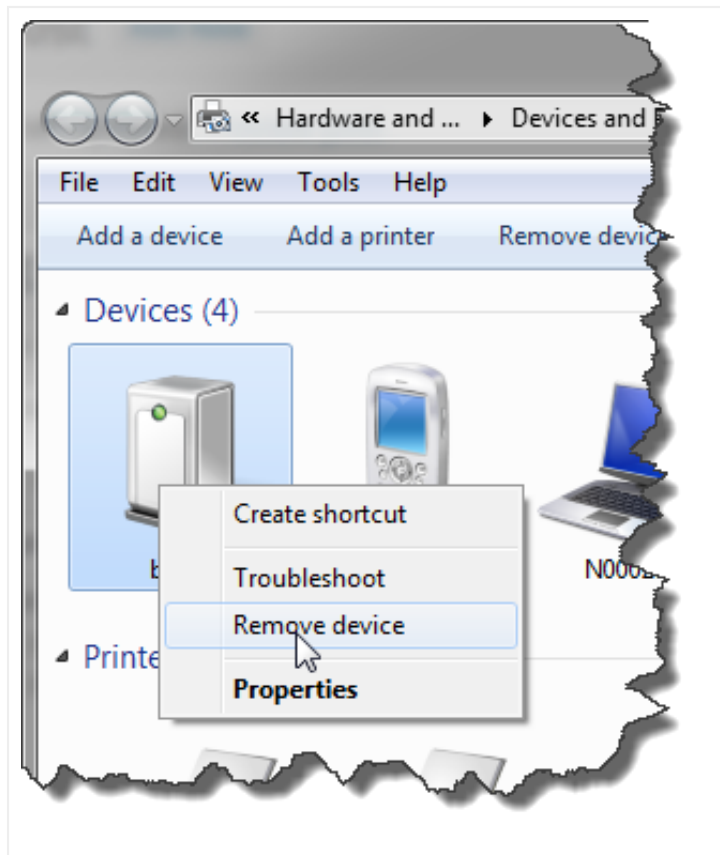

1  /**

52         (void)CLS1_ReadAndParseWithCommandTable(bTbuf, sizeof(bTbuf),
53     }
54 }

```

Unbinding and Trouble Shooting

In case there are issues with connecting to the module, it is necessary to unbind and re-bind (connect) to the module. It happened to me sometimes I'm able to connect once, but then not any more. In that case the following steps help:

1. Close any terminal program potentially connected to the Bluetooth virtual COM port.
2. Unpower the Bluetooth module so it is not visible any more to the PC.
3. Right click on the device in the Windows Device manager (or Devices and Printer group) and select 'Remove Device':

— Unbinding Bluetooth Device

4. Re-power the module: the red LED shall be blinking as not connected.
5. Search for the device in the device manager (as above), and connect again to the device with a pairing pin.
6. Connect to the module using the COM port specified for the SPP service.

That way I was always able to recover connection to my module. See as well [this post](#) which helped me to solve my problem.

Sources

All the component sources discussed are available on [GitHub](#). Additionally, the [FRDM-KL25Z Bluetooth example project](#) has been updated to support both the HC-05 and HC-06

modules.

Happy Bluetoothing 😊

139 THOUGHTS ON "USING THE HC-06 BLUETOOTH MODULE"

Alex Vecchio

on [June 19, 2013 at 21:39](#) said:

Hi Erich,

Maybe you can talk about 24L01+ and Ethernet communications? Do you have this Beans?

Thanks,

Alex Vecchio

Hi Alex,
do you mean the 24L01 from Nordic Semiconductor? No,
I do not have beans for this one. I do have an Ethernet
Shield, but had not much time to work on it. It will be one
of the next things for sure.

★ Like

Alex Vecchio

on **June 19, 2013 at 21:58** said:

Ouch... Fastest answer i`ve ever seen!

Yes. I am talking about the Nordic Semiconductor
24L01. Maybe this can be a really cheap solution
to control a freedom board from another freedom
board wirelessly.

Other thing is to control a freedom board through
the intranet.

I am waiting for your new posts. Thanks for this
excellent job you are doing.

★ Like

Erich Styger

on **June 19, 2013 at 22:38** said:

Sometimes I never sleep 😊
yes, that Nordic module is really interesting,
although I do not have one (yet). The HC-06
Bluetooth one (or the HC05) are really cheap: less
then \$10, and at least the HC-05 one can be used

to control another FRDM board.

Alex Vecchio

on **June 20, 2013 at 06:32** said:

Hi Erich,

I think we can control a lot of Freedom boards simultaneously with the 24L01+ but we cannot do this with bluetooth devices. Right?

★ Like

Erich Styger

on **June 20, 2013 at 08:03** said:

Yes, doing this with the HC-05 probably is not easily possible. For the use case you describe I'm using an IEEE802.15.4 module which can build up star or mesh networks.

Hi Erich,

These modules are really cheap at (http://yourduino.com/sunshop2/index.php?l=product_detail&p=188).

I have bought from them and the parts were very reasonable and shipping was good too!

Cheers,

Tom

on **June 21, 2013 at 07:37** said:

Hi Tom,
they are *incredibly* cheap, thanks for the link. I guess will order a few to try it out. One concern I have: the drivers I have seen are all GPL2 which is a concern. Have you seen (or using) LGPL or BSD style drivers or stacks? Otherwise it looks I need to develop everything from ground up which is not ideal.

★ Like

Tom

on **June 21, 2013 at 14:37** said:

Erich,
Erich,

No I haven't seen LGPL or BSD stacks but I haven't been looking that hard. There is a library at (<http://arduino-info.wikispaces.com/nRF24L01-RF24-Examples>) which may be something you can leverage.

★ Like

Erich Styger

on **June 21, 2013 at 14:42** said:

Hi Tom,
yes, I already found that library, but it is GPL2 as well, so not very usable for anything than true

hobby projects.

Anyway, I have ordered a handful of modules, and whenever I find time, I'll start writing a BSD style driver. Contributions are always welcome 😊

Hi Erich

I got some experience with one of these modules on a project. I think they are all more or less the same, but for the firmware (as you point out). The circuit is a CSR reference design. The CSR chip is based around a core architecture developed at Cambridge university. You can get the development tools from their web site (easy to find), and develop your own firmware for the module. I never got so far as to download all that, not sure about what the cost is etc. I would guess there is a reference design for the firmware as well, which is what all of these different firmware versions would be based upon.

Hi Dusty,
yes, I have found the article from Byron (<http://byron76.blogspot.ch/2011/09/hc05-firmware.html>) which points to the CSR site. I have registered and downloaded the tools, but not done much with it. I did not know that this has been developed at Cambridge, which is interesting.

Hi, Erich!

You have done a very good job by creating a component like this. Two weeks ago, I have bought a BC04 bluetooth module from ElectroDragon (which is a little bit different from HC05 or HC06 as firmware) and this thing involved, for me, some changes into your component source code.

After implementing all changes, I would like to add a new BC04 firmware to

“Bluetooth_EBGT” component project. The problem with that is caused by the fact that I cannot import very well your project, because when I try to edit the source code of a method I get the following error : “Source Code missing in default driver. It could be present in a prg.”.

Any help would be greatly appreciated.

Thank you.

★ Like

Erich Styger

on **July 3, 2013 at 10:40** said:

Hi Surdeanu,

I don't think I have seen that error myself, so not sure what is causing this? Maybe you could email me your changes/source code and I'm happy to have it incorporated into the Processor Expert component. Send it to the email I have listed at the end of the 'About' page of this blog.

Thanks for contributing to that project!

on [October 2, 2013 at 10:32](#) said:

Hi Erich,

thx a lot for showing the differences between HC-05 and HC-06 module !

I happened to get my HC-06 work with a Trust USB-BT dongle and WinXP32.

Just shortcut the Tx/Rx on the module and used Comport Toolkit as a terminal to see the looped back chars.

If longer blocks of data are sent the delay decreases to somewhat 90msecs. But that's all for the good news.

The HC-06 does not establish working mode (steady LED) when I use my lenovo T500 with win7-64. I can connect the device, send pairing pin and two successive COMxy ports are shown in device manager. But the first where the SPP is assigned to can not be accessed by my terminal programs and the LED on the HC-06 keeps flashing indicating AT mode 😞.

Same situation with my Galaxy-S2 GT-i9100, it finds it, pairing pin input but HC-06 stays in AT mode.

Has anyone an idea or solution about that ???

All the best, Tom.

Hi Tom,

I had some problems with another notebook, where I was not able to establish connection: here it helped to re-install the drivers on the notebook as explained in the article.

On another notebook I used a cheap bluetooth dongle (under Windows7 64bit). I never got it working to connect to the bluetooth module, while it worked on another machine with XP.

So I just make the guess that there might be a similar problem in your case, but with the internal bluetooth module? It might be worthwhile to try an external bluetooth module?

on [October 7, 2013 at 10:31](#) said:

Hi Erich,

Thanks for your comments.

With Android I've got it work. After inputting the pairing sequence on the phone the HC06 stays in AT mode but if my app runs it connects and switches to SPP mode 😊.

I'll try to reinstall the win7 BT drivers and see what will happen...

Good luck, Tom.

Erich Styger

on **December 8, 2013 at 16:12** said:

If nothing happens if you write AT commands, this typically means that the Bluetooth module already has been connected to the PC host. If the module is connected, then the LED is on (compared to be in blinking mode if not paired, where it accepts AT commands). Another reason

for the AT commands not working is a wrong UART baud configuration. By default the modules operate with 9600 baud. Please verify with a logic analyzer if that baud is used. I hope this helps?

Hi,

the HC-06 only can be slave, so you cannot connect two HC-06 with each other. It should be possible to connect a HC-06 with a HC-05 in master mode, but I have not tried this yet.

on **December 12, 2013 at 18:15** said:

Yes, some microcontrollers can configure the UART to different than 8bits (e.g. to 7 bits).

To my knowledge this is not possible with Kinetis. But I have not checked deeply on this.

Hi Diego,

are you using my example from GitHub? From the shell output it looks like you have not added the command line interface to the Bluetooth module, as it does not show up with help. Be aware that if the HC-06 LED is not blinking, the module already connected to a host, and it does not accept any AT commands (the AT commands are sent to the host).

Erich Styger

on **February 2, 2014 at 18:46** said:

Hi Jami,

yes, the module operates with 3.3V logic levels. You just need to be careful about the supply voltage. My modules say 3.6V-6V, but I was able to use them with 3.3V without problems. That might depend on the module.

on **February 7, 2014 at 23:05** said:

Excellent site, thanks, lots of good info,

I wonder if you can assist with my little challenge?

My project is to provide a wireless connection between a racing yacht's Nav computer (a B&G Hercules Performance Unit) and my Android phone using my HT-06 (Ver 1.06).

To build up some expertise, I'm practicing at home by trying to get the connection going by connecting the HT-06 to my Garmin GPS72 handheld GPS receiver. I'm bluetoothing to the HT-06 with my laptop and a cheap USB dongle using a good terminal emulator (Reflection).

When connecting the GPS72 to the laptop with a cable, it comes in on USB at COM04 and my terminal emulator happily talks to it at 4800 8/None.

However, when trying to get the laptop to talk to the GPS72 with the HT-05, I get the connection up and running (solid led) and I'm receiving data from the GPS72, but on the terminal see the pulses of data, but instead of getting interpretable data, there are strings of, like "~f~~"

I know it's because I have an incompatibility in comms protocols and have tweaked the terminal through speeds and parity with no joy.

I suspect I have to configure the HT-06 to use 4800 8/N, but not having the connectors to connect the laptop to the HT-05 I'm not able to tweak the coms speeds from the laptop, so I'm wondering if it is at all possible to send AT commands from the laptop to the HT-06 over BT?

Hi Alan,

thanks for your kind words 😊.

As for your question: you cannot send AT commands over the air to the Bluetooth module: if it is connected, it is in transparent mode and will send the incoming data to the other side (so you cannot reach the Bluetooth controller with AT commands).

As for the protocol errors: can you hook up a logic analyzer on the serial signals to see what is going on? That would give a clue if the baud is somewhat wrong or outside the spec, if parity/etc is used.

Hi Erich,

Back again, sorry.

I suspect I have a faulty device (HC-06 Ver 1.06), and being a software guy, a class world-renowned for unfairly blaming the hardware, I have tried to be thorough in my testing.

The final clincher for me is that when I send AT commands over the serial port I get no response at all.

I have a breakout board on the serial line and can see the RX line flash its led.

The HC-06 is flashing.

I am using 232Analyzer to send data 9600 8 N 1 and am sending AT.

I have read the HC Serial Bluetooth Products User Instructional Manual, <http://www.exp-tech.de/service/datasheet/HC-Serial-Bluetooth-Products.pdf> which seems quite straightforward if a little confusing.

And I'm still receiving corrupt data over the bluetooth connection when sending ASCII at 9600 8 N 1.

Before I send off for a replacement, is there anything else that you know that I can try to talk to my baby?

Cheers, and thanks for your patience.

★ Like

Erich Styger

on **February 14, 2014 at 05:46** said:

If the HC06 is flashing, then it is not connected to the PC. You really would need a logic analyzer like the Saleae one so you can inspect the bits and bytes on the line. Maybe something is wrongly configured on your side (baud?), and only with flashing LEDs you will not see it. I'm a software guy too, but developing software for hardware means a scope and a logic analyzer is key. Without it, it is like programming without a PC monitor 😞.

on **February 19, 2014 at 00:38** said:

I'm a novice with these boards as well but it appears that you're trying to send AT commands and the chip is not in that mode. My board had a pin labeled "KEY". Tie that pin to the VCC source, Now disrupt and re-establish the power to the HC-06 leaving the "Key" tied to power. The unit will reboot in AT mode. To reset to Normal mode remove KEY from Vcc and disrupt and re-establish power. I was also able to easily pair with this device using "1234" as the code. Once that was done I opened up TeraTerm Pro and selected the comm port configured for my BT. I was talking to a Mini Pro quite quickly...Hope this helps...

Hello Erich,

I am using an HC-05 board (found on eBay

[http://www.ebay.com/itm/150843209961?](http://www.ebay.com/itm/150843209961?ssPageName=STRK:MEWNX:IT&_trksid=p3984.m1497.l2649)

[ssPageName=STRK:MEWNX:IT&_trksid=p3984.m1497.l2649](http://www.ebay.com/itm/150843209961?ssPageName=STRK:MEWNX:IT&_trksid=p3984.m1497.l2649)).

I am trying to configure it using the AT commands. This can only be done using the physical serial connection to the PC, is that correct? I believe I managed to get the board into configuration mode using the KEY pin, since the LED now blinks differently. However, when I use Termite to send AT commands (simply with AT\r\n), the board responds with things such as: x, then xÅ\r\n, then Ap\ûpÿ, etc every time I resend the AT command. I guess it could be some problem with the coding of the commands such as wrong font... But still I don't understand why it responds differently to a unique command.

Can you help? Thank you in advance!

on **March 12, 2014 at 11:34** said:

I have concluded that the HC-06 device does not conform to RS232 standards.

I have spent 6 weeks messing with it (well, 2 separately purchased boards) connected to my PC (XP and W7) using some pretty clever terminal emulators (realTerm, Commfront 232Analyser, Reflection) and I have concluded that it doesn't generate the 10 bit per character (start, 8 bit data, stop) syntax defined by RS232. I was unable to get it to respond to an AT command, nor could I get it to transmit text at its default speed of 9600, N 8,1 or any other combination.

All the folks successfully using it are using Arduino. I haven't found anyone using it successfully in conventional RS232 PC mode. I have thrown them away and spent \$125 on an older but functional RS232 to Bluetooth adapter. It's pretty clunky, requiring a PC Utility to configure it, but it works!

Hi Erich,

Thanks for the reply. I don't have a logic analyzer. I have tested somewhat further and I have noticed that using Terminate, when I change the baud rate to a lower value, I get a response identical to what I send to the device. If I put a higher baud rate, I start getting all this nonsense... Also, I should mention that I don't have a serial connection on my computer, so I make use of a RS232 to USB converter from Logilink. So the baud rate which I change is probably the baud between the PC and the converter.

Just read Allan and Tom's comments. If I understand it, I should have a RS232 to TTL converter between my USB to RS232 converter and the HC-05 module because the HC-05 "talks" in TTL and not RS232?

★ Like

Erich Styger

on **March 18, 2014 at 14:54** said:

Hi Remi,
The HC-05 module does not use TTL (0-5V) levels, but 0-3.3V. RS-232 uses completely different voltage levels (3 to 15V and -3 to -15V, see <http://en.wikipedia.org/wiki/RS-232>), so they are not compatible. Your PC or RS-232-USB converter expects that different voltage, so if you want to connect the bluetooth module to your PC, then you need to use a level shifter like a Maxim 3232 or similar. The logic levels of 0-3.3V of the module are only to be used with something which has the same voltage levels, e.g. a microcontroller.

Remi Wielandts
on **March 18, 2014 at 15:18** said:

Hi Erich, thanks for the answers. The daughter board which I bought with the HC-05 module mounted on it has such a MAX3232 level shifter (see ebay link above).

I know that I was able to switch the board into AT mode, at least from the different blinking of the LED. I tried using different baud rates for the serial communication to the bluetooth module, no success. I made sure the TX and RX are correct, used different voltage levels (5.0 and 3.3 volts) for both the Vcc and the Key. I tried to reset the device using AT+RESET in case the transmission to the device was functioning correctly but not the reception from it. I have bought 3 of these devices and tested all, they give the same results.

I am running out of ideas...

Btw, what is the tiny push button on the daughter boards for?

★ Like

Erich Styger
on **March 18, 2014 at 18:10** said:

I have not used these modules. But it sounds you have nothing than the modules? No user manual, schematics or something you absolutely need to understand this module. I checked that ebay page, but there was no more information than the pictures. You even cannot be sure what kind of firmware is on the module without this information. And without the right tools (aka logic analyzer) it is like fishing in the dark 😞

★ Like

Erich Styger

on **March 18, 2014 at 18:14** said:

Oh, I see, there *is* indeed a data sheet 😊. What the 'Key' does depends on the firmware on the module. Many firmwares are using it to get back into the 'command' mode. But not clear to me which firmware really is on this module.

★ Like

Erich Styger

on **March 18, 2014 at 18:15** said:

And I have found in the description what 'key' is supposed to do. Key connects 3.3V to PIO11:
3. PIO11, control the module working mode,
High=AT commands receiving mode(Commands response mode), Low
or NC= Bluetooth module normally working.

Alan

on **March 27, 2014 at 00:48** said:

Hi Remi,

I can confirm that a Maxim 3232 works like a charm with the HC-06 to provide an interface between a PC serial COM port and the HC-06, notwithstanding the discrepancy between the TTL and MCU voltages, as it handles the voltage range of 3.3 to 5V.

I have just taken delivery of my Maxim board and am happily bluetoothing between my PC and my Android phone.

I have also connected my Garmin GPS72, configured to report using NMEA at 4800 to my Android phone with this configuration. You don't need a logic analyser. You do have to cross the TXD and RXD lines between the HC-06 and the Maxim. It's taken me almost eight weeks to work this out, but success comes to the diligent!

on **March 12, 2014 at 14:46** said:

Alan,

Sorry, but you are missing basic electrical skills and you did not rtfm.

The HC-05/6 as well as all the other BT-modules from other suppliers provide a 3,3V digital logic interface. The guys using an arduino wire the 3,3V TxD/RxD signals of the arduino UART to the corresponding pins on the HC-05 module, the arduino provides a virtual COMport via USB to the connected PC/Laptop so there is no RS232 within that signal way to be used.

Your PC (COM1:) has a standard RS232 interface what is electrically on a total different planet (use wikipedia and READ please) as the 3,3V or 5V digital logic interface. Or you use an USB->RS232 converter cable but that's the same...

That's why you could not make a working connection... It is an electrical problem !

http://www.ebay.de/itm/RS232-Serial-Port-to-TTL-Digital-Converter-Module-SP3232EEN-5V-3-3V-Jump-Kables-/400676853830?pt=Wissenschaftliche_Ger%C3%A4te&hash=item5d4a339846

Use something like that and everything should be fine ;o).

Good luck, tom.

on **March 30, 2014 at 16:20** said:

Hi erich

I have a module (DAQ Module) to get data from strain gage in rotating sensor. The module use USB cable communication to my computer (It has Ft232 serial to Usb IC in its daughterboard). Now, I want to get the data via Bluetooth, and I already bought HC 05. Unfortunately, Because of the module architecture, I can't get its rx tx to my HC 05.

In the HC 05 datasheet, I see the USB Dp and Dm port, and they said it can transfer data via usb protocol (v 1.1). After that, I connect my module's USB port (USB type B) to the Dp and the Dm port, and I connect the Vcc and Gnd to my power bank. The HC 05 is connected to my comp, but it is connected to my Serial Com over the Bluetooth, not as the module it self. And i cant connect the module to my Labview (because the module is used to connect via USB cable)

I want to ask several questions:

- Can I connect HC 05 via USB Protocol, instead of UART Serial Communication?
- What should I do if I want to connect via USB protocol? Install another driver (in windows device manager)for my HC 05, or else?

I'm sorry for my long post and my english. Hope to get your response soon

Thank you 😊

Hi Harvey,

To my knowledge, only the SPI port

(<http://byron76.blogspot.ch/2011/09/upgrade-your-bluetooth-module.html>) is active for the HC-05 module. I don't think it is able to talk the USB protocol unless you have a different firmware on it. And if your module would indeed have the firmware for USB on it: which device class would it implement? Moreover, to connect it to USB, it would need the proper protection/etc which I do not see implemented on the module? So my thinking is that you cannot connect the module directly to USB: to connect it to USB you need to have a SCI-to-USB converter. Like that FT232 or simply use the FRDM-KL25Z board with an USB firmware to implement a USB-CDC bridge (<http://mcuoneclipse.com/2012/10/07/tutorial-usb-cdc-with-the-kl25z-freedom-board/>).

I hope this helps?

on **March 30, 2014 at 18:22** said:

Hi Erich

Thank you for your kindness to answer me.

I'm sorry, maybe my explanation about my module is not good enough yet

My module is Emant 300. It is used to be connected to computer physically with usb cable, but actually communicate with the computer using UART. So that's why there is converter of USB-TTL (FT232) in my module.

You can see it in this link <http://www.emant.com/251004.page>

I have tried to connect my module via usb cable, and it was detected (until now, it is, as long as i connect it via usb cable). In Windows Device Manager, its name is USB serial port (to proof it physically connect via usb cable, but talking with serial communication). It connected to my Labview, detected as emant 300 DAQ module.

But now, I want to change usb cable with bluetooth HC 05. So i cut the usb cable, pin Dp and Dm to HC 05, and power it with power bank. But why the bluetooth can't connect as USB Protocol?

About SCI to USB converter, I will try to learn that. Maybe it will provide me another alternatives. Thank you, Erich

★ Like

Erich Styger

on **March 30, 2014 at 19:03** said:

Are you saying that you connected Dp and Dm to the HC05 Rx/Tx pins? This for sure does not work: USB is using a completely different protocol than RS-232/SCI. Not only this, it is using different voltage levels too.

★ Like

akselsmandel

on **March 30, 2014 at 19:31** said:

No, I am not. I connected Dp and dm to the HC 05 Dp and Dm pins, since it have those pins. I want to communicate usb protocol via bluetooth but it doesn't work 😞

Maybe the manufacturer must delete its spec about 'can use usb protocol v. 1,1' . They does not have the explanation about that (and make me confused). HC 05 Users in internet don't talk about this too, so it's hard to find any clue about usb protocol over bluetooth on it.

Maybe i'll try to convert the usb protocol to serial protocol, as you say, and after that connect that serial to the Rx/Tx pin at HC 05

Thank you very much, Erich

Hi Erich,

A great and interesting article on the bluetooth modules..!! And I must say, your comments section is full of lost of additional info..!! I would like to ask help for my small problem with the HC-06 module, which seems similar to Tom.

I'm on Vista with the default bluetooth stack/drivers. I have a cheap bluetooth dongle adapter as my laptop doesn't have native BT hardware. I have followed the numerous procedures for paring-powerup-power cycle-unplug replug device- etc etc, but none seem to get the hc-06 to connect with my PC.

The computer sees the BT device fine, it seemingly pairs. Atleast the windows dialog box shows that and device drivers are installed. I can also see the com ports in device properties and in device manager. But the status LED on the module keeps blinking indicating AT mode and never goes solid on.

The serial port shows up in the services tab of the BT device properties, but when I try to connect to the serial port in any terminal emulator (I tried a few of them to be sure), it either stops responding or tells port not found or closed etc. Checking the services tab again afterwards confirms this (the serial port has disappeared from the list momentarily). If I unpair / repair / power cycle the module, same thing happens over again.

There doesn't seem to be anything wrong with the module itself, as I can pair it with 2 separate smart-phones. Everything works correctly as I can see serial data coming in from the microcontroller, and also issue commands to the microcontroller over BT.

Thanks in advance for your help.

Kind regards,

Ameya.

on **July 30, 2014 at 19:11** said:

Hi Ameya,

thanks for your kind words 😊.

About your problem: just installing the drivers on the host

will not change the blinking LED. The blinking LED only gets permanently on once you have a connection to the module with a terminal program. The fact that your terminal emulator stops responding indicates to me that you might be using the wrong COM port? At least I have the same on my machine (which has a native BT module). Pay attention that there are multiple USB COM ports installed by the driver, but only one works (the one which is listed in the properties of the device driver, <http://mcuoneclipse.files.wordpress.com/2013/06/device-services.png?w=584>). So can you make sure you connect to the proper COM port with your terminal program?

I hope this helps.

on **August 4, 2014 at 11:35** said:

Hello Erich,

Thanks for your prompt help..!! I am sure I am using the correct port in the terminal emulator. The HC-06 enumerates with 2 ports, only one is available in SPP mode and thats the one I use to connect. Here is some more surprising behavior I came across.

1. Firstly, "sometimes" I am able to successfully connect and send-receive data..!!
2. But then majority of the times, it refuses to connect after paring. When that happens, LED is blinking, terminal emulator reports port closed or stops responding, and SPP device disappears from the Bluetooth device properties.
3. I then have to remove device, power-cycle HC-06 module, re-pair and try to re-connect again. But 90% of the times it never works. I just get plain lucky the remaining 10% times, and proceed with my actual work.
4. I may get going again after a restart of the PC, but that also is not consistent. Yesterday I tried installing other BT drivers PC side, but of no use.
5. Also, all these times I keep checking the

module functionality periodically, by successfully pairing and connecting with an android smart phone, which works as expected.

I strongly feel its the PC side BT stack which is messing things up. Can you suggest something here..??

Kind regards,
Ameya.

Hi,
thank you for this article !
I have the same problem as Ameya, i can pair the HC-06 to my computer (Windows 8.1 x64, Qualcomm Atheros AR3012 Bluetooth module), i can see the SPP profile at first, but it doesn't get to connect with any software, and when i tried once to connect, the SPP profile disappear from the list of services...
Did you find a solution ?

Thanks

Ben

Hi Ben,

I'm using Windows 7 64bit, so I'm not sure if this is a Windows 8.x issue? I can tell that on my machine it shows two different COM ports, but only one is working. Using the other COM port fails. Maybe you have two COM ports listed too and you are using the wrong one? Just a guess.

Hi,

it may be a Win8.x issue yes..

I'm used to deal with BT Virtual serial ports on windows (with other chips, not Low Energy), i know about the 2 COM ports creation and that only one is ok.

This is really strange because the service is there at first and then, poof ! nothing listed anymore...

On a smartphone, this works just fine.

Hello Erich,

I have bought an HC-05 mounted on a daughter board that allows me to communicate in RS232 with the module instead of TTL (it has the MAX3232 chip).

I use the module to communicate between a PC and a motion controller (Elmo) in RS232. I was able to change the communication parameters to suit me (baud rate, flow control and parity). I was able to establish a connection with the controller through the software that was delivered with it.

Only I noticed that the connection is very unstable: I am either unable to establish a connection at the first attempt or the connection drops after between 5 and 60 seconds. I decided to analyze the communication between the PC and the controller by using Termite. I look at what is transmitted by the PC when a connection is attempted and what the controller responds.

I noticed that the connection fails or drops when the controller's response contains errors. These are sorts of typos in the answers from the controller. Do you think this could come from the module ? Or does it look more like noise, or a bad connection to earth level ? Any ideas ?

Thanks!

Hi Remi,

I would first verify the power connection to the module. Is it within specs? 5V? Then: maybe the UART connection from the microcontrolle is the problem: if your clock is drifting, or not stable enough, you will get garbage on the serial line. you would need to check this with a scope or logic analyzer. And you might need to use a lower baud rate (I use all my modules with the default baud rate of 9600 or 38400 (depends on module)).

on **August 5, 2014 at 11:02** said:

Hi Erich,

I use a USB port for the 5V supply, just for convenience. Maybe this is not the best thing to do. I will have a try with my DC controlled power supply instead.

I do not have a logic analyzer available but will look for one in case this does not fix the problem. Also, I had the module set to a baud rate of 115200 since this is the default baud of the controller. I have now lowered it back to 9600 and at first sight, the connection looks more stable than before. It will need some more testing but it looks better already!

Thanks a lot!

Hi. I have huge problem with HC 06. I changed name, pin and baud rate with AT commands... but then the module is not working... It doesnt respond to any AT commands and when I am connected to module with.. for example.. android device and I try to send some AT commands... It doesnt read any characters..... Please.. help me 😞 thanks

You need to use a microcontroller board (like the FRDM-KL25Z I used) to regain access to the module.

Use the same baud as you have specified. If that does not work, it could be that the baud settings are incorrect: try with the microcontroller all defined baud rates of the module, and use a logic analyzer to inspect the result.

Then you should be able to recover the module.

good luck!

I'm affraid, that without a logic analyzer, you will not be able to go far in your development and programming.

A logic analyzer is as important as your screen for programming: without it, you cannot see what is going on.

I wrote a tutorial how you could build your own logic analyzer:

<http://mcuoneclipse.com/2013/02/03/turning-the-freedom-board-into-a-logic-analyzer/>

Hi, there is really no magic behind doing something like this:

- a) check that button is pressed (several ways to do this)
- b) send a message/string/command to the UART to the Bluetooth module
- c) that message/string/command will end up on the Android phone connected to the bluetooth module
- d) it is up to you what you do with this message on the Android side.

I hope this helps,
Erich

Hi Erich

I want to connect two Bluetooth modules HC-05: one with a microprocessor (I will use raspberry Pi B+) and the other with a suitable microcontroller that will control a relay for 220v devices

...

1. What is the microcontroller that you recommend it for this job??
2. Is this process possible and easy for 100 (or more) slaves and one master??
3. On what version is the HC-05 Bluetooth Module work??

Best wishes, and thanks alot

Hi Abdallah,

1. You can use pretty much any microcontroller which has a SCI/UART. I'm using the Freescale Kinetis KL family for most of my projects, like the one in this post (FRDM-KL25Z).
2. I have not used such a configuration, but for sure the master will be limited in the number of connections it can maintain. I think 100 is far too much. Probably you can have only up to 8 connections. This might be specified in the Bluetooth standard.

3. Not sure about this question? I have not used the HC05 in master mode.

I hope this helps,
Erich

Hi Erich,

Thanks for the very useful write up. I am currently, stuck at a problem – I have an HC-05 and configure it to be a slave in serial profile. However, the module that is feeding the data to HC-05 (to be transmitted) does NOT send a newline character (“\n”) at the

end of its payload. As a result, the HC-05 does not transmit the data! Do you think there might be a way around this – if I needed to, could I update the firmware on HC-05 to support this? Or maybe the HC-06 does not wait for a newline character before transmitting and I could shift to an HC-06?

Thanks,
NK2020

on **April 5, 2015 at 11:23** said:

Hi NK2020,
you need that '\n', otherwise it will not work. And you cannot configure this. There is a way to update the firmware (see <http://byron76.blogspot.ch/2011/09/upgrade-your-bluetooth-module.html>), but in your case you would need to change the firmware which itself is not open/available. So better if you change the things on your end and make sure that '\n' is used. HC-05 and HC-06 both need '\n'

Thank you very much for your response, Erich. I am interfacing an EM-18 RFID card reader to HC-05, and the tragedy is that the EM-18 does not send \n after every card ID that it transmits (over UART to the HC-05). The only option I see (if I want to stick to these two modules) is to have a small uC in between. AArrghh 😊

Thanks again for your help.

-NK2020.

Hii.

I am trying to make communication between two Uno boards via HC-05 ..

I have established the connection between them n hc05 are paired properly.

But when I send the data from any of the device it display the garbage value.

I didn't get it..

Plz help me out so that I can make proper transfer of data.

hello Erich,
you helped many people – please help me too

I have connected HC-06 to my existing STM32 microcontroller board

I have bought bluetooth dongle and installed it to my computer – it showed HC-06 as bluetooth devices and entered pin and connected to it so on

I didnot give any AT command from my STM32 and used my same old communication software between my PC (XP) and STM32 (9600 8N1)

the control center of the PC shows 3 serial ports COM8 COM9 and COM10 added

I choosed COM10 and when my software started the red LED on the HC-08 stop blinking and always ON – so I succesfully connected to HC-06

now I send 10 byte packet to my STM32 with checksum to “run” the STM32 – it runs its green LED is blinking when I send “stop” packet it “stops” its green LED always ON

this far everything good

however my PC software is expecting a reply from STM32 and this doesnot come – the PC software says no communication

I am sure my 10 byte packet received by the STM32 because it “runs” or “stops” according to the command packet

and my STM32 is preparing a reply packet to PC in 20 – 30 microseconds after the PC command received

I could not find any answer to this problem – is there a delay of HC-06 from receiving to sending or vice versa ?

I didnot changed any AT command regarding baud rate – is not HC-06 9600 8N1 by default ?

how can you help ?

thank you

on **May 25, 2015 at 16:19** said:

Hi Mehmet,

a few tips:

- make sure you have RX/TX lines correctly connected: maybe you have mixed them up?
- the default firmware on my HC-06 module is using 9600 baud. BUT: it could be that you have one with a different firmware.
- use a logic analyzer to see what the module response is (if any). You might try with different baud rates too.
- have you debugged the code on the STM32? I fear you are using 'LED debugging' only which will not help you much. Use a debugger to see if you really receive data properly.
- you say you have COM8, COM9 and COM10: make sure you use that port listed in the Bluetooth driver properties on your PC as outlined in this blog post.
- You can change the baud rate of the module, but only if you have a working connection to the bluetooth module.

I hope this helps,

Erich

HC-06 board provides TorquePro OBDII guages for projects. I use EV Display on Android phone easily. When I try in windows 8.1 to pair I succeed. I can also access one of the two com ports and issue AT Commands like:

AT+SETUP

AT+AH

And can set variables accordingly:

AT+AH=384

AT+END

What I was hoping I could use the terminal for was to view the data that must be getting sent over bluetooth the torquepro apk.

I am running an adroid emulator and of course I learn after I ran the trial for a few days and decided it was cool and purchased that in the end they don't have bluetooth and probably won't ever. Sad day to spend \$30.00 on apps and none provide the functionality. Would rather have kicked in to a kickstarter for the emulator problem than have it buy cigs and beer for someone etc...

I have every terminal program available and would like to see the data if it is possilbe otherwise please advise and will have to find another solution for marine state of charge guages for windows computers.
